F3-08AD-1 8-Channel Analog Input

In This Chapter. . . .

- Module Specifications
- Setting the Module Jumpers
- Connecting the Field Wiring
- Module Operation
- Writing the Control Program

6-28-2024 F3-08AD-1 Retired, no replacement available.

Module Specifications

The following table provides the specifications for the F3–08AD Analog Input Module from FACTS Engineering. Review these specifications to make sure the module meets your application requirements.

| Number of Observato | O single and d (and a series) |
|--------------------------|--|
| Number of Channels | 8, single ended (one common) |
| Input Ranges | 4 – 20 mA |
| Resolution | 12 bit (1 in 4096) |
| Input Impedance | $250\Omega \pm 0.1\%$, 1/2W current input |
| Absolute Maximum Ratings | ±30mA |
| Conversion Time | 35μs per channel 1 channel per CPU scan |
| Converter Type | Successive Approximation, AD574 |
| Linearity Error | ±1 count (0.03% of full scale) maximum |
| Maximum Inaccuracy | 0.35% of full scale at 77 °F (25 °C) |
| Accuracy vs. Temperature | 57 ppm / °C maximum full scale (including maximum offset change of 2 counts) |
| Recommended Fuse | 0.032 A, Series 217 fast-acting |
| Power Budget Requirement | 25 mA @ 9 VDC, 37 mA @ 24 VDC |
| External Power Supply | None required |
| Operating Temperature | 32° to 140° F (0° to 60° C) |
| Storage Temperature | -4° to 158° F (-20° to 70° C) |
| Relative Humidity | 5 to 95% (non-condensing) |
| Environmental air | No corrosive gases permitted |
| Vibration | MIL STD 810C 514.2 |
| Shock | MIL STD 810C 516.2 |
| Noise Immunity | NEMA ICS3-304 |
| | |

Analog Input Configuration Requirements

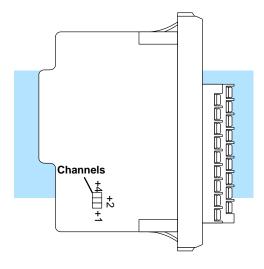

The F3–08AD Analog Input appears as a 16-point module. The module can be installed in any slot configured for 16 points. See the DL305 User Manual for details on using 16 point modules in DL305 systems. The limitation on the number of analog modules are:

• For local and expansion systems, the available power budget and 16-point module usage are the limiting factors.

Setting the Module Jumpers

Jumper Locations

The module is set at the factory for a 4–20 mA signal on all eight channels. If this is acceptable you do not have to change any of the jumpers. The following diagram shows how the jumpers are set.

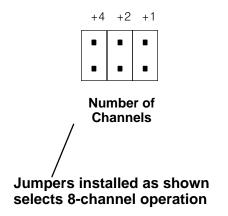

Selecting the Number of Channels

If you examine the rear of the module, you'll notice several jumpers. The jumpers labeled +1, +2 and +4 are used to select the number of channels that will be used. Without any jumpers the module processes one channel (channel 1). By installing the jumpers you can add channels. The module is set from the factory for eight channel operation.

For example, if you install the +1 jumper, you add one channel for a total of two. Now if you install the +2 jumper you add two more channels for a total of four.

Any unused channels are not processed so if you only select channels 1–4, then the last four channels will not be active. The following table shows which jumpers to install.

| Channel(s) | +4 | +2 | +1 |
|------------|-----|-----|-----|
| 1 | No | No | No |
| 1 2 | No | No | Yes |
| 123 | No | Yes | No |
| 1234 | No | Yes | Yes |
| 12345 | Yes | No | No |
| 123456 | Yes | No | Yes |
| 1234567 | Yes | Yes | No |
| 12345678 | Yes | Yes | Yes |

Connecting the Field Wiring

Wiring Guidelines

Your company may have guidelines for wiring and cable installation. If so, you should check those before you begin the installation. Here are some general things to consider.

- Use the shortest wiring route whenever possible.
- Use shielded wiring and ground the shield at the signal source. Do not ground the shield at both the module and the source.
- Don't run the signal wiring next to large motors, high current switches, or transformers. This may cause noise problems.
- Route the wiring through an approved cable housing to minimize the risk of accidental damage. Check local and national codes to choose the correct method for your application.

User Power Supply Requirements

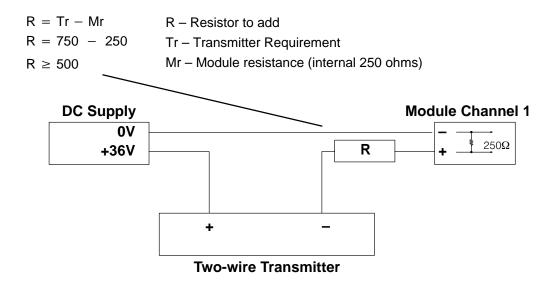

The F3-08AD receives all power from the base. A separate power supply is not required.

Current Loop Transmitter Impedance

Standard 4 to 20 mA transmitters and transducers can operate from a wide variety of power supplies. Not all transmitters are alike and the manufacturers often specify a minimum loop or load resistance that must be used with the transmitter.

The F3-08AD provides 250 ohm resistance for each channel. If your transmitter requires a load resistance below 250 ohms, then you do not have to make any adjustments. However, if your transmitter requires a load resistance higher than 250 ohms, then you need to add a resistor in series with the module.

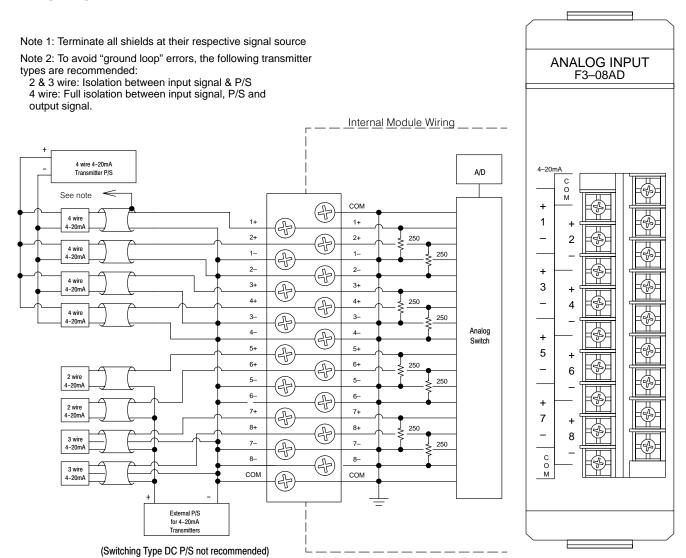

Consider the following example for a transmitter being operated from a 36 VDC supply with a recommended load resistance of 750 ohms. Since the module has a 250 ohm resistor, you need to add an additional resistor.

Removable Connector

The F3–08AD module has a removable connector to make wiring easier. Simply squeeze the top and bottom tabs and gently pull the connector from the module.

Wiring Diagram

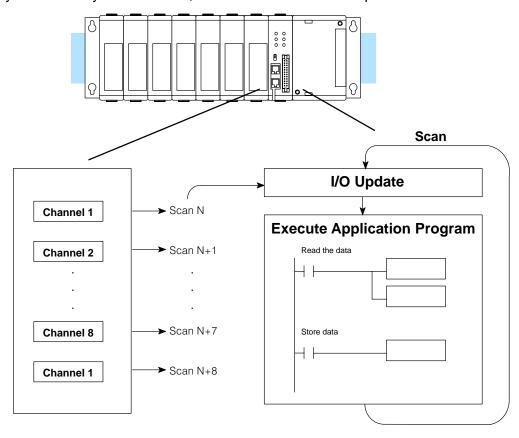

Module Operation

Before you begin writing the control program, it is important to take a few minutes to understand how the module processes and represents the analog signals.

Channel Scanning Sequence

The F3–08AD module supplies1 channel of data per each CPU scan. Since there are eight channels, it can take up to eight scans to get data for all channels. Once all channels have been scanned the process starts over with channel 1.

You do not have to select all of the channels. Unused channels are not processed, so if you select only four channels, then the channels will be updated within four scans.

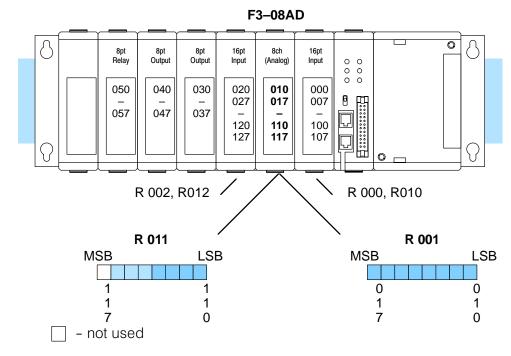

Even though the channel updates to the CPU are synchronous with the CPU scan, the module asynchronously monitors the analog transmitter signal and converts the signal to a 12-bit binary representation. This enables the module to continuously provide accurate measurements without slowing down the discrete control logic in the RLL program.

Understanding the I/O Assignments

You may recall the F3–08AD module appears to the CPU as a 16-point module. These 16 points provide:

- an indication of which channel is active.
- the digital representation of the analog signal.

Since all I/O points are automatically mapped into Register (R) memory, it is very easy to determine the location of the data word that will be assigned to the module.

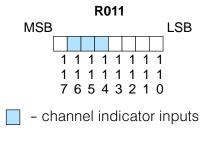

Within these two register locations, the individual bits represent specific information about the analog signal.

Active Channel Indication Inputs

The next to last three bits of the upper Register indicate the active channel. The indicators automatically increment with each CPU scan.

| <u>Scan</u> | Channel Inputs | Active Channel |
|-------------|----------------|----------------|
| N | 000 | 1 |
| N+1 | 001 | 2 |
| N+2 | 010 | 3 |
| N+3 | 011 | 4 |
| N+4 | 100 | 5 |
| N+5 | 101 | 6 |
| N+6 | 110 | 7 |
| N+7 | 111 | 8 |
| N+8 | 000 | 1 |

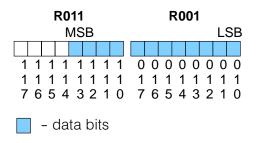

Analog Data Bits

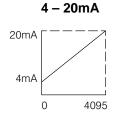

The remaining twelve bits represent the analog data in binary format.

| Bit | <u>Value</u> | <u>Bit</u> | <u>Value</u> |
|---------|--------------|------------|--------------|
| 0 (LSB) | 1 | 6 | 64 |
| 1 | 2 | 7 | 128 |
| 2 | 4 | 8 | 256 |
| 3 | 8 | 9 | 512 |
| 4 | 16 | 10 | 1024 |
| 5 | 32 | 11 | 2048 |

Since the module has 12-bit resolution, the analog signal is converted into 4096 "pieces" ranging from 0-4095 (2^{12}). For example, with a 4-20 mA scale, a 4 mA signal would be 0, and a 20 mA signal would be 4095. This is equivalent to a binary value of 0000 0000 0000 to 1111 1111 1111, or 000 to FFF hexadecimal. The following diagram shows how this relates to each signal range.

Each "piece" can also be expressed in terms of the signal level by using the equation shown. The following table shows the smallest signal levels that will result in a change in the data value for each signal range.

Resolution = $\frac{H - L}{4095}$

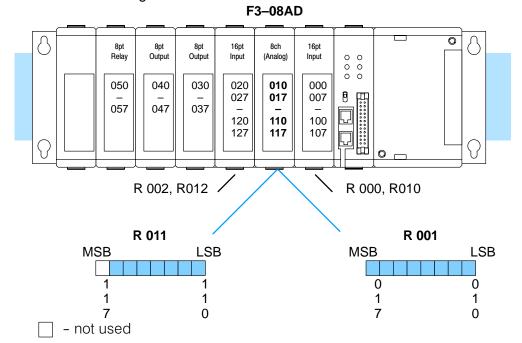

H = high limit of the signal range L = low limit of the signal range

| Range | Highest Signal | Lowest Signal | Smallest Change |
|-----------|----------------|---------------|-----------------|
| 4 to 20mA | 20mA | 4mA | 3.91 μΑ |

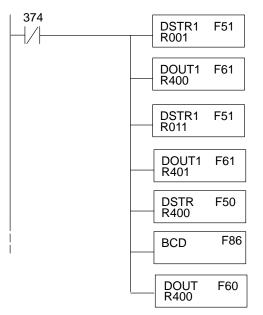

Now that you understand how the module and CPU work together to gather and store the information, you're ready to write the control program.

Writing the Control Program (DL330 / DL340)

Identifying the Data Locations Since all channels are multiplexed into a single data word, the control program must be setup to determine which channel is being read. Since the module provides input points to the CPU, it is very easy to use the active channel status bits to determine which channel is being monitored.

Single Channel on Every Scan The following example shows a program that is designed to read a single channel of analog data into a Register location on every scan. Once the data is in a Register, you can perform math on the data, compare the data against preset values, etc. This example is designed to read channel 1. Since you use jumpers to select the number of channels to scan, this is the only channel that you can use in this manner.

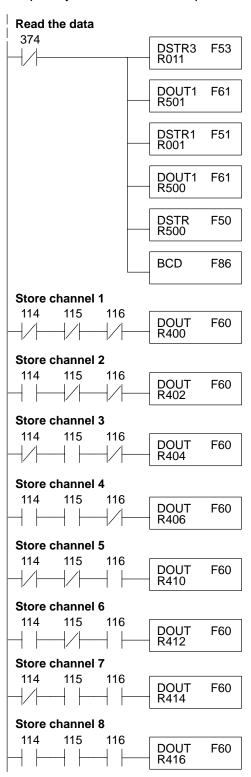

This rung loads the data into the accumulator on every scan. (You can use any permissive contact.)

Since the active channel indicators are all off when channel 1 is being read, you would not have to use them. (Since you cannot isolate the individual channels for scanning, channel 1 is the only channel that can be used in this manner.) The DOUT1 instruction moves the data to a storage register. The BCD value will be stored in R400 and R401. (Two bytes are required for four digit BCD numbers.)

The DL305 CPUs perform math operations in BCD. This instruction converts the binary data to BCD. (You can omit this step if your application does not require the conversion.)

Reading Multiple Channels over Alternating Scans

The following example shows a program designed to read any of the available channels of analog data into Register locations. Once the data is in a Register, you can perform math on the data, compare the data against preset values, etc. Since the DL305 CPUs use 8-bit word instructions, you have to move the data in pieces. It's simple if you follow the example.

This rung loads the four most significant data bits into the accumulator from Register 011 on every scan. (You could use any permissive contact.)

Temporarily store the bits to Register 501.

This rung loads the eight least significant data bits into the accumulator from Register 001.

Temporarily store the bits to Register 500. Since the most significant bits were loaded into 501, now R500 and R501 contain all twelve bits in order.

Now that all the bits are stored, load all twelve bits into the accumulator.

Math operations are performed in BCD. This instruction converts the binary data to BCD. (You can omit this step if your application does not require the conversion.)

The channel indicator inputs are used to let the CPU know which channel has been loaded into the accumulator. By using these inputs to control a DOUT instruction, you can easily move the data to a storage register. Notice the DOUT instruction stores the data in two bytes. (Two bytes are required for four digit BCD numbers.)

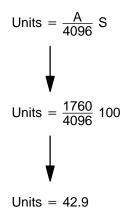

Scaling the Input Data

Most applications usually require measurements in engineering units, which provide more meaningful data. This is accomplished by using the conversion formula shown.

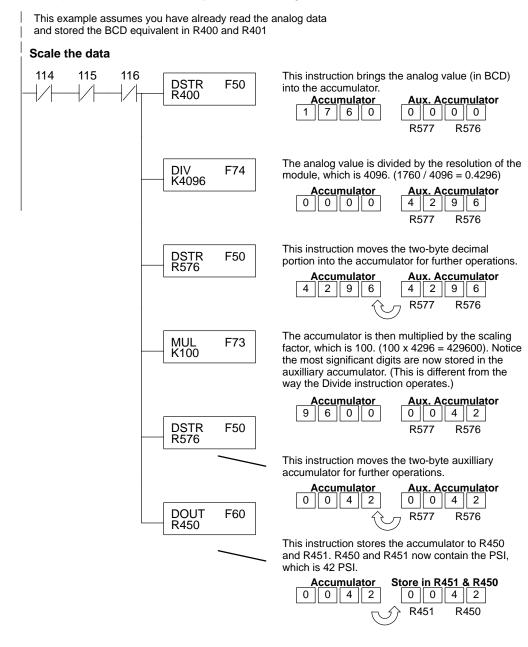

The following example shows how you would use the analog data to represent pressure (PSI) from 0 to 100. This example assumes the analog value is 1760. This should yield approximately 42.9 PSI.

Units =
$$\frac{A}{4096}$$
 S

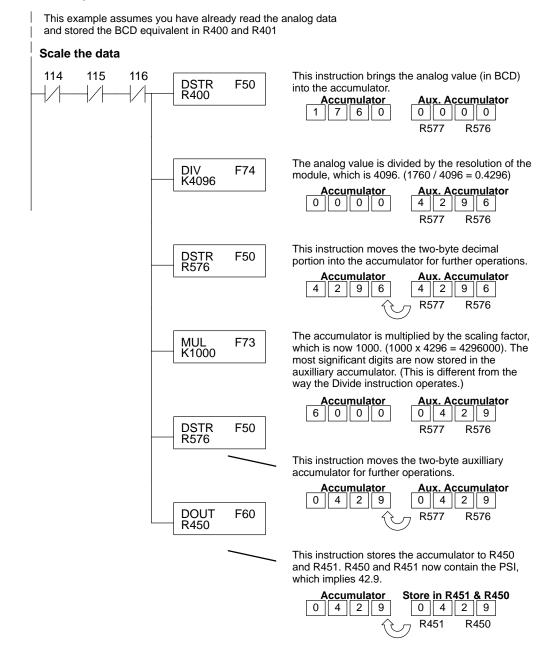

Units = value in Engineering Units A = Analog value (0 - 4095)S = high limit of the Engineering unit range

The following instructions are required to scale the data. We'll continue to use the 42.9 PSI example. In this example we're using channel 1. Input 114, input 115, and input 116 are all off when channel 1 data is being read. Of course, if you were using a different channel, you would use the active channel indicator point combination that corresponds to the channel you were using.

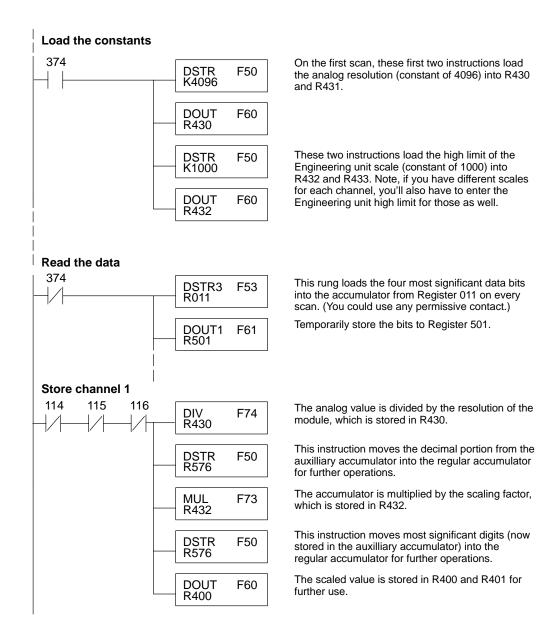

You probably noticed the previous example yielded 42 PSI when the real value should have been 42.9 PSI. By changing the scaling value slightly, we can "imply" an extra decimal of precision. Notice in the following example we've added another digit to the scale. Instead of a scale of 100, we're using 1000, which implies 100.0 for the PSI range.

This example program shows how you can use the instructions to load these equation constants into data registers. The example was written for channel 1, but you could easily use a similar approach to use different scales for all channels if required.

You could just use the appropriate constants in the instructions dedicated for each channel, but this method allows easier modifications. For example, you could easily use an operator interface or a programming device to change the constants if they are stored in Registers.

F3-08AD-1 8-Channel Analog Inpu

Writing the Control Program (DL350)

Reading Values: Pointer Method and Multiplexing

There are two methods of reading values for the DL350:

- The pointer method (all system bases must be D3-xx-1 bases to support the pointer method)
- Multiplexing

You must use the multiplexing method with remote I/O modules (the pointer method will not work). You can use either method when using DL350, but for ease of programming it is strongly recommended that you use the pointer method.

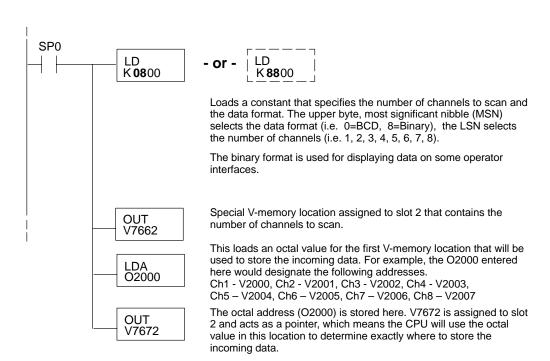

NOTE: Do not use the pointer method and the PID PV auto transfer from I/O module function together for the same module. If using PID loops, use the pointer method and ladder logic code to map the analog input data into the PID loop table.

Pointer Method

The DL350 has special V-memory locations assigned to each base slot that greatly simplifies the programming requirements. These V-memory locations allow you to:

- specify the data format
- specify the number of channels to scan
- · specify the storage locations

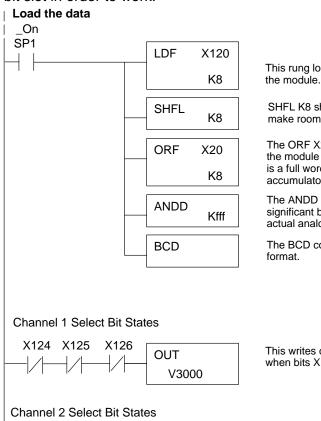

The example program shows how to setup these locations. Place this rung anywhere in the ladder program or in the Initial Stage if you are using RLL PLUS instructions. This is all that is required to read the data into V-memory locations. Once the data is in V-memory, you can perform math on the data, compare the data against preset values, and so forth. V2000 is used in the example, but you can use any user V-memory location. In this example the module is installed in slot 2. You should use the V-memory locations for your module placement.

The table shows the special V-memory locations used with the DL350. Slot 0 (zero) is the module next to the CPU, slot 1 is the module two places from the CPU, and so on. Remember, the CPU only examines the pointer values at these locations after a mode transition. The pointer method is supported on expansion bases up to a total of 8 slots away from the DL350 CPU. The pointer method is not supported in slot 8 of a 10 slot base.

| Analog Input Module Slot-Dependent V-memory Locations | | | | | | | | |
|---|-------|-------|-------|-------|-------|-------|-------|-------|
| Slot | 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| No. of Channels | V7660 | V7661 | V7662 | V7663 | V7664 | V7665 | V7666 | V7667 |
| Storage Pointer | V7670 | V7671 | V7672 | V7673 | V7674 | V7675 | V7676 | V7677 |

Multiplexing: DL350 with a Conventional DL305 Base The example below shows how to read multiple channels on an F3–08AD Analog module in the X20–27 / X120–127 address slot. This module must be placed in a 16 bit slot in order to work.

This rung loads the upper byte of analog data from the module.

SHFL K8 shifts the data to the left eight places to make room for the lower byte of data.

The ORF X20 brings the lower byte of data from the module into the accumulator. At this time there is a full word of data from the analog module in the accumulator.

The ANDD Kfff masks off the twelve least significant bits of data from the word. This is the actual analog value.

The BCD command converts the data to BCD format

This writes channel one analog data to V3000 when bits X124, X125 and X126 are as shown.

This writes channel two analog data to V3001 when bits X124, X125 and X126 are as shown.

Channel 3 Select Bit States

This writes channel three analog data to V3002 when bits X124, X125 and X126 are as shown.

example continued on next page

Channel 4 Select Bit States

This writes channel four analog data to V3003 when bits X124, X125 and X126 are as shown.

Channel 5 Select Bit States

This writes channel five analog data to V3004 when bits X124, X125 and X126 are as shown.

Channel 6 Select Bit States

This writes channel six analog data to V3005 when bits X124, X125 and X126 are as shown.

Channel 7 Select Bit States

This writes channel seven analog data to V3006 when bits X124, X125 and X126 are as shown.

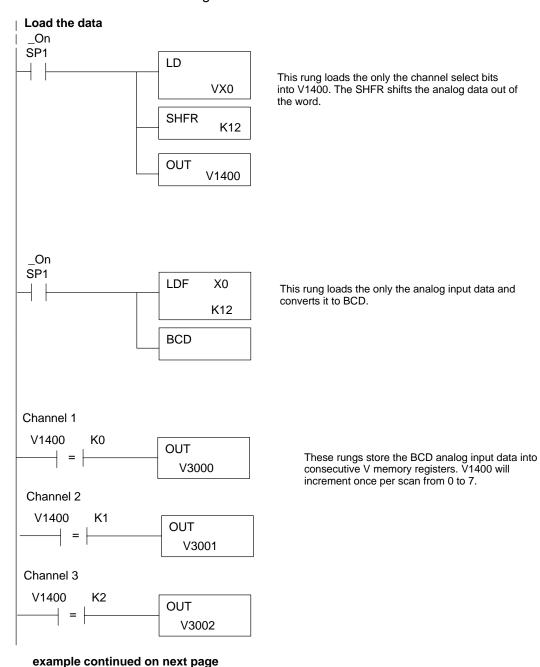

Channel 8 Select Bit States

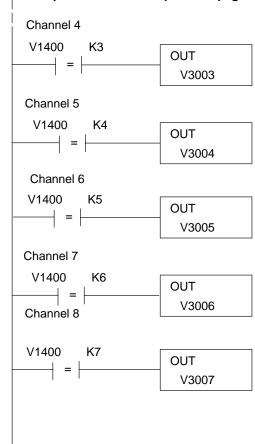

This writes channel eight analog data to V3007 when bits X124, X125 and X126 are as shown.

Multiplexing: DL350 with a D3-xx-1 Base

The example below shows how to read multiple channels on an F3–08AD Analog module in the X0 address slot of a D3–xx–1 base. If any expansion bases are used in the system, they must all be D3–xx–1 to be able to use this example. Otherwise, the conventional base addressing must be used.

example continued from previous page

These rungs store the BCD analog input data into consecutive V memory registers. V1400 will increment once per scan from 0 to 7.

Scaling the **Input Data**

applications usuallv Most require measurements in engineering units, which provide more meaningful data. This is accomplished by using the conversion formula shown.

You may have to make adjustments to the formula depending on the scale you choose for the engineering units.

Units = A
$$\frac{H - L}{4095}$$

H = high limit of the engineering unit range

L = low limit of the engineering unit range

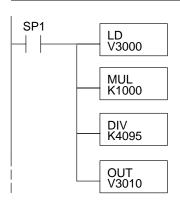

A = Analog value (0 - 4095)

For example, if you wanted to measure pressure (PSI) from 0.0 to 99.9 then you would have to multiply the analog value by 10 in order to imply a decimal place when you view the value with the programming software or a handheld programmer. Notice how the calculations differ when you use the multiplier.

Here is how you would write the program to perform the engineering unit conversion. This example assumes you have BCD data loaded into the appropriate V-memory locations using instructions that apply for the model of CPU you are using.

NOTE: This example uses SP1, which is always on. You could also use an X, C, etc. permissive contact.

When SP1 is on, load channel 1 data to the accumulator.

Multiply the accumulator by 1000 (to start the conversion).

Divide the accumulator by 4095.

Store the result in V3010.

Analog and Digital Sometimes it is helpful to be able to quickly convert between the signal levels and the Value Conversions digital values. This is especially helpful during machine startup or troubleshooting. The following table provides formulas to make this conversion easier.

| Range | If you know the digital value | If you know the analog signal level |
|-----------|-------------------------------|-------------------------------------|
| 4 to 20mA | $A = \frac{16D}{4095} + 4$ | $D = \frac{4095}{16}(A - 4)$ |

For example, if you have measured the signal at 10mA, you would use the following formula to determine the digital value that should be stored in the register location that contains the data.

$$D = \frac{4095}{16}(A - 4)$$

$$D = \frac{4095}{16} (10 \text{mA} - 4)$$

$$D = (255.93)(6)$$

$$D = 1536$$
